Problem Set 6

1. Polynomials with no roots [15 points]

A polynomial p(x) of degree n over a field F has at most n roots. But it does not need to have n roots, nor it must have roots at all.

- (a) Write all polynomials in GF_2 having no roots over GF_2 .
- (b) Write all polynomials in GF_3 having no roots over GF_3 .
- (c) Find a polynomial p(x) which has roots over GF_3 , but not over Z.

2. What secrets?[25 points]

In our exposition of secret sharing, we always set the secret to be P(0), i.e. the constant term of the polynomial P used to generate the keys in the field GF(q).

- (a) Could the scheme be generalized to have the secret chosen to be P(k) for k such that 0 < k < q?
- (b) More concretely, suppose now that q = 7, k = 2 and P has degree 2. Given P(1) = 5; P(3) = 6, P(4) = 5, use Lagrange's Interpolation to recover the secret P(k).
- (c) Finally, suppose q = 7, k = 0 and P has degree 2, but this time you are given p(1) = 3; P(3) = 4; P(4) = 2. Use Lagrange's Interpolation to recover the secret P(0). Now, can you see why P(0) is a good choice for the secret?

3. How many secrets?[30 points]

A secret sharing scheme is k-secure if and only if any group of k or fewer people has probability at most 1/q of recovering the secret, where q is the number of possible choices for the secret (this means that the best strategy such a group has is to guess the secret at random). In the typical secret sharing scheme, the secret is P(0), the value of a certain degree k polynomial (that we construct) at 0. Suppose that, instead, the secret is P(0), P(1) (the values at both 0 and 1). Is this scheme still k-secure? Prove your answer.

4. Error Correcting Code[30 points]

In this question we will go through an example of error-correcting codes. Since we will do this by hand, the message we will send is going to be short, consisting of n = 3 numbers, each modulo 5, and the number of errors will be k = 1.

- (a) First, construct the message. Let $a_0 = 4$ and $a_1 = 3$, $a_2 = 2$; then use the polynomial interpolation formula to construct a polynomial P(x) of degree 2 (remember that all arithmetic is mod 5) so that $P(0) = a_0$, $P(1) = a_1$, and $P(2) = a_2$; then extend the message to length N + 2k by adding P(3) and P(4). What is the polynomial P(x) and what are P(3) and P(4)?
- (b) Suppose the message is corrupted by changing a_0 to 0. Use the Berlekamp-Welsh method to find a polynomial g(x) of degree 2 that passes through 4 of the 5 points. Show all your work.
