Full Example – Sort in C (pg. 133)

```
void sort (int v[], int n)
{
   int i, j;
   for (i=0; i<n; i+=1) {
      for (j=i-1; j>=0 && v[j] > v[j+1]; j-=1) {
        swap (v,j);
      }
   }
}
```

```
void swap (int v[], int k)
{
   int temp;
   temp = v[k];
   v[k] = v[k+1];
   v[k+1] = temp;
}
```

- Allocate registers to program variables
- Produce code for the program body
- Preserve registers across procedure invocations

The swap Procedure

 Register allocation: \$a0 and \$a1 for the two arguments, \$t0 for the temp variable – no need for saves and restores as we're not using \$s0-\$s7 and this is a leaf procedure (won't need to re-use \$a0 and \$a1)

```
swap: sll $t1, $a1, 2
add $t1, $a0, $t1
lw $t0, 0($t1)
lw $t2, 4($t1)
sw $t2, 0($t1)
sw $t0, 4($t1)
jr $ra
```

```
void swap (int v[], int k)
{
   int temp;
   temp = v[k];
   v[k] = v[k+1];
   v[k+1] = temp;
}
```

The sort Procedure

- Register allocation: arguments v and n use \$a0 and \$a1, i and j use
 \$s0 and \$s1; must save \$a0 and \$a1 before calling the leaf procedure
- The outer for loop looks like this: (note the use of pseudo-instrs)

```
move $s0, $zero # initialize the loop loopbody1: bge $s0, $a1, exit1 # will eventually use slt and beq ... body of inner loop ... addi $s0, $s0, 1 j loopbody1 exit1:
```

```
for (i=0; i<n; i+=1) {
  for (j=i-1; j>=0 && v[j] > v[j+1]; j-=1) {
    swap (v,j);
  }
}
```

The sort Procedure

• The inner for loop looks like this:

```
addi $s1, $s0, -1 # initialize the loop
               $s1, $zero, exit2 # will eventually use slt and beq
loopbody2: blt
          sll $t1, $s1, 2
          add $t2, $a0, $t1
          lw $t3, 0($t2)
          lw $t4, 4($t2)
          ble $t3, $t4, exit2
          ... body of inner loop ...
          addi $s1, $s1, -1
                 loopbody2
                                    for (i=0; i<n; i+=1) {
exit2:
                                      for (j=i-1; j>=0 \&\& v[j] > v[j+1]; j-=1) {
                                         swap (v,j);
                                                                          11
```

Saves and Restores

- Since we repeatedly call "swap" with \$a0 and \$a1, we begin "sort" by copying its arguments into \$s2 and \$s3 – must update the rest of the code in "sort" to use \$s2 and \$s3 instead of \$a0 and \$a1
- Must save \$ra at the start of "sort" because it will get over-written when we call "swap"
- Must also save \$s0-\$s3 so we don't overwrite something that belongs to the procedure that called "sort"

Saves and Restores

```
sort: addi $sp, $sp, -20
         $ra, 16($sp)
     SW
     sw $s3, 12($sp)
                                9 lines of C code \rightarrow 35 lines of assembly
     sw $s2, 8($sp)
     sw $s1, 4($sp)
     sw $s0, 0($sp)
     move $s2, $a0
     move $s3, $a1
            $a0, $s2 # the inner loop body starts here
     move
            $a1, $s1
     move
     jal
            swap
          $s0, 0($sp)
exit1: lw
           $sp, $sp, 20
     addi
                                                                     13
            $ra
     jr
```

IA-32 Instruction Set

- Intel's IA-32 instruction set has evolved over 20 years –
 old features are preserved for software compatibility
- Numerous complex instructions complicates hardware design (Complex Instruction Set Computer – CISC)
- Instructions have different sizes, operands can be in registers or memory, only 8 general-purpose registers, one of the operands is over-written
- RISC instructions are more amenable to high performance (clock speed and parallelism) – modern Intel processors convert IA-32 instructions into simpler micro-operations

Endian-ness

Two major formats for transferring values between registers and memory

Memory: low address 45 7b 87 7f high address

Little-endian register: the first byte read goes in the low end of the register

Register: 7f 87 7b 45

Most-significant bit / Least-significant bit (x86)

Big-endian register: the first byte read goes in the big end of the register

Register: 45 7b 87 7f

Most-significant bit / Least-significant bit (MIPS, IBM)

Binary Representation

The binary number

```
represents the quantity 0 \times 2^{31} + 1 \times 2^{30} + 0 \times 2^{29} + ... + 1 \times 2^{0}
```

- A 32-bit word can represent 2³² numbers between
 0 and 2³²-1
 - ... this is known as the unsigned representation as we're assuming that numbers are always positive

ASCII Vs. Binary

- Does it make more sense to represent a decimal number in ASCII?
- Hardware to implement arithmetic would be difficult
- What are the storage needs? How many bits does it take to represent the decimal number 1,000,000,000 in ASCII and in binary?

ASCII Vs. Binary

- Does it make more sense to represent a decimal number in ASCII?
- Hardware to implement arithmetic would be difficult
- What are the storage needs? How many bits does it take to represent the decimal number 1,000,000,000 in ASCII and in binary?

In binary: 30 bits $(2^{30} > 1 \text{ billion})$

In ASCII: 10 characters, 8 bits per char = 80 bits

Negative Numbers

32 bits can only represent 2^{32} numbers – if we wish to also represent negative numbers, we can represent 2^{31} positive numbers (incl zero) and 2^{31} negative numbers

Why is this representation favorable?

Consider the sum of 1 and -2 we get -1

Consider the sum of 2 and -1 we get +1

This format can directly undergo addition without any conversions!

Each number represents the quantity

$$x_{31} - 2^{31} + x_{30} 2^{30} + x_{29} 2^{29} + ... + x_1 2^1 + x_0 2^0$$

Note that the sum of a number x and its inverted representation x' always equals a string of 1s (-1).

$$x + x' = -1$$

 $x' + 1 = -x$... hence, can compute the negative of a number by
 $-x = x' + 1$ inverting all bits and adding 1

Similarly, the sum of x and -x gives us all zeroes, with a carry of 1 In reality, $x + (-x) = 2^n$... hence the name 2's complement

Example

• Compute the 32-bit 2's complement representations for the following decimal numbers:

Example

• Compute the 32-bit 2's complement representations for the following decimal numbers:

Given -5, verify that negating and adding 1 yields the number 5

Signed / Unsigned

The hardware recognizes two formats:

unsigned (corresponding to the C declaration unsigned int)

-- all numbers are positive, a 1 in the most significant bit just means it is a really large number

signed (C declaration is signed int or just int)

-- numbers can be +/- , a 1 in the MSB means the number is negative

This distinction enables us to represent twice as many numbers when we're sure that we don't need negatives

MIPS Instructions

```
Consider a comparison instruction:
slt $t0, $t1, $zero
and $t1 contains the 32-bit number 1111 01...01
```

What gets stored in \$t0?

MIPS Instructions

```
Consider a comparison instruction:
slt $t0, $t1, $zero
and $t1 contains the 32-bit number 1111 01...01
```

What gets stored in \$t0?

The result depends on whether \$11 is a signed or unsigned number – the compiler/programmer must track this and accordingly use either slt or sltu

```
slt $t0, $t1, $zero stores 1 in $t0 sltu $t0, $t1, $zero stores 0 in $t0
```

Sign Extension

- Occasionally, 16-bit signed numbers must be converted into 32-bit signed numbers – for example, when doing an add with an immediate operand
- The conversion is simple: take the most significant bit and use it to fill up the additional bits on the left – known as sign extension

Alternative Representations

- The following two (intuitive) representations were discarded because they required additional conversion steps before arithmetic could be performed on the numbers
 - sign-and-magnitude: the most significant bit represents
 +/- and the remaining bits express the magnitude
 - one's complement: -x is represented by inverting all the bits of x

Both representations above suffer from two zeroes
