# The Online Median Problem

---

Guntash Arora  
April 30, 2015

## 1 PROBLEM STATEMENT

**Definition 1.** A  $\lambda$  - approximate metric  $d$  satisfies following relaxed triangle inequality  
For any sequence of points

$$x_0, x_1, x_2 \dots x_m$$
$$d(x_0, x_m) \leq \lambda * \sum_{0 \leq i < m} d(x_i, x_{i+1})$$

holds.

### 1.1 PROBLEM STATEMENT

Objective of online median problem is to output a total ordering on  $U$ . So, if we want to solve k-median problem, we pick first k elements of this ordering

- Cost function is same as that of k-median problem
- Input : A set of points  $U$  and  $\lambda$  - approximate metric  $d$
- Output : A total ordering on  $U$

**Definition 2.** *Competitive Ratio* : It is maximum over all possible choices of input instances and  $k$ , of ratio of cost of center given by first  $k$  element of this ordering to that of optimal  $k$  centers.

## 2 ALGORITHM

### 2.1 DEFINITIONS

- Let

$$\lambda, \alpha, \beta, \gamma$$

denote four real numbers satisfying following inequalities

$$\lambda \geq 1$$

$$\alpha > 1 + \lambda$$

$$\beta \geq \frac{\lambda(\alpha - 1)}{\alpha - \lambda - 1}$$

$$\gamma \geq \left( \frac{\alpha^2 \beta + \alpha \beta}{\alpha - 1} + \alpha \right) \lambda$$

- Value of ball  $A = (x, r)$  is

$$\sum_{y \in A} (r - d(x, y)) * w(y)$$

- Child of ball  $A = (x, r)$  is any ball  $(y, \frac{r}{\alpha})$  such that  $d(x, y) \leq \beta r$ . Note that  $(x, \frac{r}{\alpha})$  is also a child of A.
- $isolated(x, \phi)$  is  $(x, \max_{y \in U} d(x, y))$
- $isolated(x, X)$ , where X is non-empty set, is  $(x, \frac{d(x, X)}{\gamma})$
- For any non-empty list  $\sigma$ ,  $head(\sigma)$  and  $tail(\sigma)$  denote first and last element of list  $\sigma$ , respectively

### 2.2 ALGORITHM

Let  $Z_0 = \phi$ . For  $i = 0$  to  $n-1$ , execute the following steps

1. list  $\sigma_i = \{A\}$ , where A is maximum value ball in  $\{isolated(x, Z_i) | x \in U\}$
2. while  $tail(\sigma_i)$  has more than one child, append its maximum value child at the end of  $\sigma_i$ .
3.  $Z_{i+1} = Z_i \cup \{center(tail(\sigma_i))\}$ .

## 3 COMPETITIVE RATIO ANALYSIS

We will try to prove the following theorem, which bounds the ratio of cost between chosen centers and any arbitrary set of centers by  $2\lambda(\gamma + 1)$ .

**Theorem 1.** For any configuration X,  $cost(Z_{|X|}) \leq 2\lambda(\gamma + 1)cost(X)$

### 3.1 SOME MORE DEFINITIONS

- Let  $z_i$  is added in  $i^{th}$  iteration.
- $Cost(X,Y) = \sum_{y \in Y} d(y, X) * w(y)$
- Let  $cell(x,X)$  for any point  $x \in X$  is  $\{y|y \in U, d(y, x) = d(y, X)\}$
- For any configuration  $X$ , point  $x$  in  $X$  and a set  $Y$ ,  $in(x,X,Y)$  is  $cell(x, X) \cap isolated(x, Y)$  and  $out(x,X,Y)$  is  $cell(x, X) \setminus in(x, X, Y)$ .
- For any configuration  $X$  and a set  $Y$ ,  $in(X,Y)$  is  $\bigcup_{x \in X} in(x, X, Y)$  and  $out(X,Y)$  is  $U \setminus in(X, Y)$ .

### 3.2 MAIN LEMMAS

Notice that we can rewrite  $cost(Z_{|X|}, U)$  as  $cost(Z_{|X|}, in(X, Z_{|X|})) + cost(Z_{|X|}, out(X, Z_{|X|}))$  and  $cost(X, U)$  as  $cost(X, in(X, Z_{|X|})) + cost(X, out(X, Z_{|X|}))$ . Now Using lemma 2,4 and 5, we can obtain the theorem mentioned above.

**Lemma 1.** For any configuration  $X$ , point  $x \in X$ , and point  $y$  in  $out(x, X, Z_{|X|})$ ,  $d(y, Z_{|X|}) \leq \lambda(\gamma + 1).d(y, X)$

**Lemma 2.**  $cost(Z_{|X|}, out(X, Z_{|X|})) \leq \lambda(\gamma + 1).cost(X, out(X, Z_{|X|}))$

**Lemma 3.** For any configuration  $X$  and a point  $x$  in  $X$ ,  $cost(Z_{|X|}, in(x, X, Z_{|X|})) \leq \lambda(\gamma + 1)[cost(X, in(x, X, Z_{|X|})) + value(isolated(x, Z_{|X|}))]$

**Lemma 4.**  $cost(Z_{|X|}, in(X, Z_{|X|})) \leq \lambda(\gamma + 1)[cost(X, in(X, Z_{|X|})) + \sum_{x \in X} value(isolated(x, Z_{|X|}))]$

We can obtain lemma 1 and 3 by writing relaxed triangle inequality and using definitions of  $in(X, Z_{|X|})$  and  $out(X, Z_{|X|})$ . Lemma 2 and 4 can be obtained by summing up the equations in lemma 1 and 3 over all  $x \in U$ .

**Lemma 5.** For any configuration  $X$ ,  $\sum_{x \in X} value(isolated(x, Z_{|X|})) \leq cost(X)$

### 3.3 PROOF OF LEMMA 5

#### 3.3.1 OVERVIEW OF PROOF

**Definition 3.** A ball  $(x,r)$  is covered iff  $d(x, X) < r$

**Lemma 6.** For any uncovered ball  $A$ ,  $cost(X, A) \geq value(A)$

Now to prove lemma 5, we will try to map element of  $X$  to some uncovered ball in  $\{\sigma_i, 0 \leq i < k\}$ . Let  $\pi$  be this mapping. We will try to ensure that these uncovered ball satisfy following properties.

1. For any pair of distinct points  $x$  and  $y$  in  $X$ ,  $\pi(x) \cap \pi(y) = \emptyset$ .

2. For any point  $x$  in  $X$ ,  $value(\pi(x)) \geq value(isolated(x, Z_k))$ .

Notice that by property 1 and lemma 6, we have  $cost(X) \geq \sum_{x \in X} value(\pi(x))$ . By property 2, we have that  $\sum_{x \in X} value(\pi(x)) \geq \sum_{x \in X} value(isolated(x, Z_{|X|}))$ . This will give prove lemma 5.

In order to satisfy property 1, we first prune all the list such no two ball in two distinct list intersect with each other. By intersection of two balls  $(x,r)$  and  $(y,s)$ , it is meant that  $d(x, y) \leq r + s$ . To do pruning, we make use of following lemmas,

**Lemma 7.** *Let  $A = (x,r)$  belong to  $\sigma_i$ . Then,  $d(x, Z_i) \geq \gamma r$*

If  $A$  is  $head(\sigma_i)$ , then above lemma is true by definition. For any arbitrary element in list, we can prove by induction on its position in the list.

**Lemma 8.** *Let  $A = (x,r)$  belong to  $\sigma_i$  and  $B = (y,s)$  belong to  $\sigma_j$ . If  $i < j$  and  $d(x, y) \leq r + s$ , then following holds*

1.  $radius(head(\sigma_i)) \leq \frac{r}{\alpha}$
2.  $A \neq tail(\sigma_i)$
3. *the successor  $A$  in  $\sigma_i$ , call it  $C$ , satisfies  $value(C) \geq value(head(\sigma_j))$*

Let  $\tau_i$  be the list obtained after pruning. In a single pruning step, if some ball  $A$  in  $\sigma_i$  intersect with some ball  $B$  in  $\sigma_j$ , we set  $\tau_i$  to suffix of  $\sigma_i$  starting at the successor of  $A$  in  $\sigma_i$ . Notice that since  $A \neq tail(\sigma_i)$ , successor of any such  $A$  always exist. Then following holds,

**Lemma 9.** *Let  $A = (x,r)$  belong  $\tau_i$  and  $B = (y,s)$  belong to  $\tau_j$ . Then if  $i < j$ ,  $d(x,y) > r+s$*

**Lemma 10.** *Each sequence  $\tau_i$  is non-empty*

Both lemmas follow from definition of the pruning.

Following lemmas establish relationship between  $value(head(\tau_i))$  and  $value(isolated(x, Z_k))$ .

**Lemma 11.** *Let  $x$  be a point and assume that  $0 \leq i < j \leq n$ . Then  $value(isolated(x, Z_i)) \geq value(isolated(x, Z_j))$*

This is trivially true because  $Z_i \subset Z_j$ .

**Lemma 12.** *Let  $x$  be a point and assume that  $0 \leq i < k$ . Then  $value(head(\sigma_i)) \geq value(isolated(x, Z_k))$*

If  $x \in Z_i$ , then RHs is zero, so we have nothing to prove. Else,  $value(head(\sigma_i)) \geq value(isolated(x, Z_i)) \geq value(isolated(x, Z_k))$ , by using definition of head of  $\sigma_i$  and lemma 11.

**Lemma 13.** *Let  $x$  be a point and assume that  $0 \leq i < k$ . Then  $value(head(\tau_i)) \geq value(isolated(x, Z_k))$*

We prove that the claim holds before and after each iteration of the pruning procedure. Initially,  $\tau_i = \sigma_i$  and the claim holds by Lemma 12. If the claim holds before an iteration of the pruning procedure, then it holds after the iteration by part 3 of Lemma 8.

### 3.3.2 MAPPING CONSTRUCTION

Let  $I$  denote set of all indices  $i$  in  $\{k\}$  such that some ball in  $\tau_i$  is covered.

Step 1:

1. Map each  $i$  in  $I$  to a point  $x \in X$  belonging to last covered ball in  $\tau_i$
2. Map each  $i$  in  $\{k\} \setminus I$  to any unmatched point in  $X$ .

Step 2:

1. Map each  $x$  that is matched to an index  $i$  in  $\{k\} \setminus I$  to  $\text{head}(\tau_i)$ .
2. Map each  $x$  that is matched to an index  $i$  in  $I$  to successor of last covered ball in  $\tau_i$ . If last covered ball is  $\text{tail}(\tau_i)$ , then map  $x$  to  $A = (x, 0)$ .

Let  $\pi$  be the final mapping. Now property 1 holds because in pruned lists, now two balls intersect. For property 2, it is each to see that for each  $x$  that is matched to an index in  $\{k\} \setminus I$ , property 2 is true using lemma 13. Otherwise, if the last covered ball in  $\tau_i$  is the tail and  $x \in \text{tail}(\tau_i)$ , then tail will have another child. This implies that  $x$  is the center of tail and  $x \in Z_{i+1}$ , so RHS is 0. If not, then predecessor of  $\pi(x)$ , say  $(y, r)$ , exists and contains  $x$ . Consider a ball  $B = (x, \frac{r}{\alpha})$ . Let  $C = (x, s) = \text{isolated}(x, Z_k)$ . Then, we claim that  $\frac{r}{\alpha} \geq s$ , which implies  $C \subset B$  and  $\text{value}(B) \geq \text{value}(C)$ . First  $d(x, z_i) \geq \gamma s$ , by definition of  $C$ . Also,

$$\begin{aligned}
 d(x, z_i) &\leq \lambda[d(x, y) + d(y, z_i)] \\
 &\leq \lambda r + \beta \lambda \left( r + \frac{r}{\alpha} + \dots \right) \\
 &\leq \left( 1 + \frac{\alpha \beta}{\alpha - 1} \right) \lambda r
 \end{aligned} \tag{3.1}$$

Last quantity is less than  $\frac{\gamma r}{\alpha}$  by definition of  $\gamma$ . This proves the fact that mapping that we created satisfies both properties and hence proof of lemma 5 is complete.
