

Both accept

$$(00)^* = L(M_1) = L(M_2)$$

- (i) Is there a minimum state machine for a Reg Lang L ?
- (ii) How are all minimum state machines for L related?

What happens if we club states of machine - say $[A, C]$ and $[B, D]$

This is similar to M_2

accepts $(00)^*$

What if we club $[A, B]$ and $[C, D]$?

When and how can we club states together and obtain a legitimate DFA for language L ?

Two strings $x, y \in \Sigma^*$ will behave similarly in future if $\delta(q_0, x) = \delta(q_0, y)$ since $\delta(q_0, x \cdot z) = \delta(q_0, y \cdot z) \quad \forall z \in \Sigma^*$

So states club together strings whose future behavior w.r.t. concatenation is same — in particular either both are accepted or both are rejected.

R_M ————— This relation is an equivalence relation since it satisfies $x R_M x$, $x R_M y \Rightarrow y R_M x$ and $x R_M y$ and $y R_M z \Rightarrow x R_M z$

R_{M_1}

A \in	B 0
C $00+(00)^*$	D $000+(00)^*$

R_{M_2}

E $(00)^*$	F $0+(00)^*$
------------	--------------

A special class of equivalence relation for strings in Σ^*

$x \sim y$, $x, y \in \Sigma^*$ are "equivalent" under a right invariant property if $\forall z \in \Sigma^*$ $x \sim y \Rightarrow x \cdot z \sim y \cdot z$

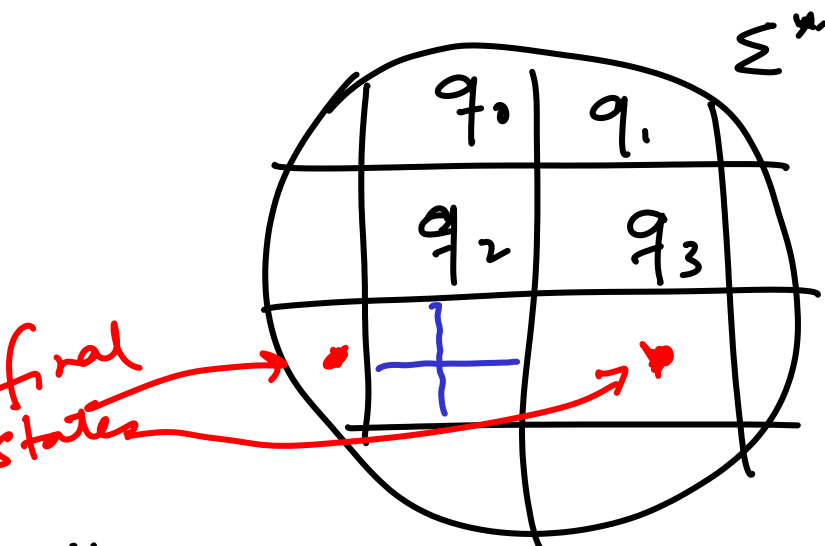

Intuition: Given a DFA, M , all string $w \in \Sigma^*$ such that $\hat{\delta}(q_0, w) = q'$

$x \sim_M y$ if $\hat{\delta}(q_0, x) = \hat{\delta}(q_0, y)$

This equivalence reln \sim_M is right invariant since $\hat{\delta}(q_0, x \cdot z) = \hat{\delta}(q_0, y \cdot z) \forall z$

Why is \sim_M transitive?

If $x \sim y$ $y \sim z \Rightarrow x \sim z$

Any equivalence relation on a set partitions the elements into (disjoint) equivalence classes

Equivalence classes of $\sim_M = |Q|$

Can we achieve a reduction in the number of states (equivalence classes) for a given regular language

- ① What is the min no. of equivalence classes - related to minimum state DFA for a language L ?
- ② Is this machine "unique"?

We want to lighten our defn of the equivalence relation in the following way

$$x \sim_L y \quad \text{iff} \quad \forall z \in \Sigma^* \quad x \cdot z \sim_L y \cdot z$$

The relation that we had defined on the basis of the machine does not force

$x \sim y$ even if $xz \sim yz$
 $\forall z \in \Sigma^*$

R_L : relation for a language L

Myhill Nerode Relation

$x R_L y$ iff $\forall z \in \Sigma^*$ either $x.z$ and $y.z$ are both in L or both are not in L .

R_M : for a specific DFA \mathcal{A} L

Claim R_L is right invariant equivalence relation

Why is it equivalence?
 reflexive, symmetric : obvious
 transitive $x R_L y \quad y R_L z$
 $\Rightarrow x R_L z$

R.I. if $x R_L y$ then $\forall z \in \Sigma^* x.z R_L y.z$

We know that for all $z' \in \Sigma^*$

$x \cdot z'$ and $y \cdot z'$ are both in L
or not in L

from defn of $x R_L y$

We want to show that $\forall u \in \Sigma^*$

$x \cdot u R_L y \cdot u$ or in other words

$\forall z \in \Sigma^*$ $xu \cdot z$ and $yu \cdot z$ are both
in L or not in L

→ Choose $z' = uz$

The equivalence classes of the relation R_L for a regular language correspond to the states of min state DFA

Myhill Nerode Theorem

A language L is regular iff
the no. of equivalence classes of R_L
is finite.

For proof we will go thru an indirect construction using R_M

The following statements are equivalent

1. L is a regular language
2. L is the union of some number of equivalence classes of a right invariant equivalence reln. of finite index ($\#$ equivalence classes is finite)
3. R_L has finite index \checkmark

$\textcircled{1} \Rightarrow \textcircled{2} \Rightarrow \textcircled{3} \Rightarrow \textcircled{1}$

Whenever $x R_M y \Rightarrow x R_L y$

$\# \text{ eqv classes of } R_L \leq \# \text{ eqv classes of } R_M$

$x R_M y \Rightarrow \exists z \in \Sigma^*$
 $x \cdot z R_M y \cdot z$ (property of right inv.)

So either both xz are in L or not in L
 $\Rightarrow x R_L y$

⑤ \Rightarrow ⑦ in Given R_L with finite index, we will construct a DFA for L .

Let $[x]$ denote the equivalence class of any string $x \in \Sigma^*$

$$M = (Q, q_0, F, \delta)$$

\downarrow
 the equiv. classes of R_L $[\epsilon]$

$$\delta([x], a) = [x \cdot a]$$

Is it consistent? \because if $y \in [x]$ is $[ya] = [xa]$ (by R.1.)

F : A state $[x]$ is accepting state if $x \in L$

We must justify that M accepts exactly L

$$\hat{\delta}([\epsilon], x) \in F \text{ iff } x \in L$$

" $[x]$ by our previous defn of $\hat{\delta}$

$$\text{So } [x] \in F \text{ iff } x \in L \quad \text{Q.E.D}$$
